

CSC 553 Operating Systems

Lecture 9 - Uniprocessor Scheduling

Types of Scheduling

Long-term scheduling	The decision to add to the pool of processes to be executed
Medium-term scheduling	The decision to add to the number of processes that are partially or fully in main memory
Short-term scheduling	The decision as to which available process will be executed by the processor
I/O scheduling	The decision as to which process's pending I/O request shall be handled by an available I/O device

Processor Scheduling

- Aim is to assign processes to be executed by the processor in a way that meets system objectives, such as response time, throughput, and processor efficiency
- Broken down into three separate functions:
 - Long term scheduling
 - Medium term scheduling
 - Short term scheduling

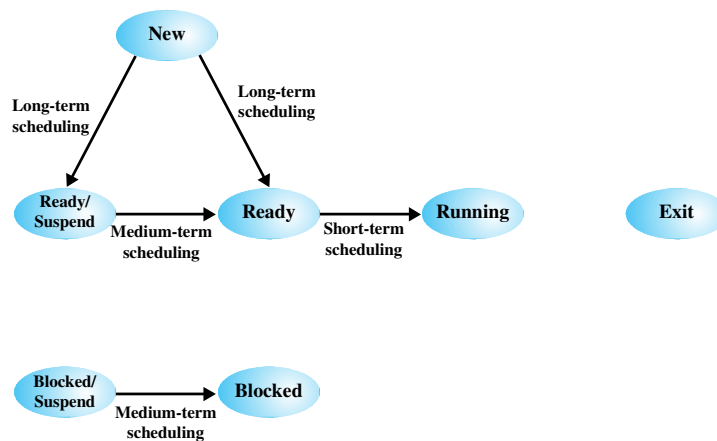

Figure 9.1 Scheduling and Process State Transitions

Long-term vs. Medium-term vs. Short-term

- Long-term scheduling is performed when a new process is created.
 - This is a decision whether to add a new process to the set of processes that are currently active.
- Medium-term scheduling is a part of the swapping function.
 - This is a decision whether to add a process to those that are at least partially in main memory and therefore available for execution.
- Short-term scheduling is the actual decision of which ready process to execute next.

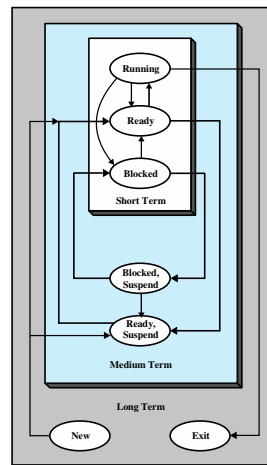

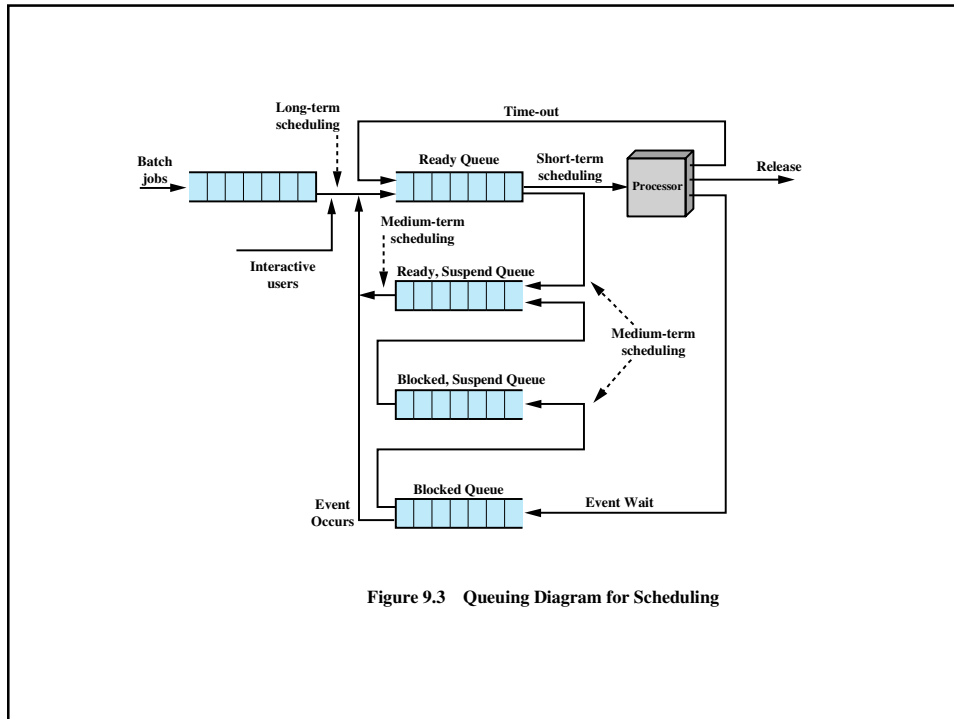

Figure 9.2 Levels of Scheduling

Long-Term Scheduler

- Determines which programs are admitted to the system for processing
- Controls the degree of multiprogramming
 - the more processes that are created, the smaller the percentage of time that each process can be executed
- may limit to provide satisfactory service to the current set of processes

Long-Term Scheduler

- Creates processes from the queue when it can, but must decide:
 - when the operating system can take on one or more additional processes
 - which jobs to accept and turn into processes
 - first come, first served
 - priority, expected execution time, I/O requirements

Medium-Term Scheduling

- Part of the swapping function
- Swapping-in decisions are based on the need to manage the degree of multiprogramming
 - considers the memory requirements of the swapped-out processes

Short-Term Scheduling

- Known as the dispatcher
- Executes most frequently
- Makes the fine-grained decision of which process to execute next

Short-Term Scheduling

- Invoked when an event occurs that may lead to the blocking of the current process or that may provide an opportunity to preempt a currently running process in favor of another
- Examples:
 - Clock interrupts
 - I/O interrupts
 - Operating system calls
 - Signals (e.g., semaphores)

Short Term Scheduling Criteria

- Main objective is to allocate processor time to optimize certain aspects of system behavior
- A set of criteria is needed to evaluate the scheduling policy

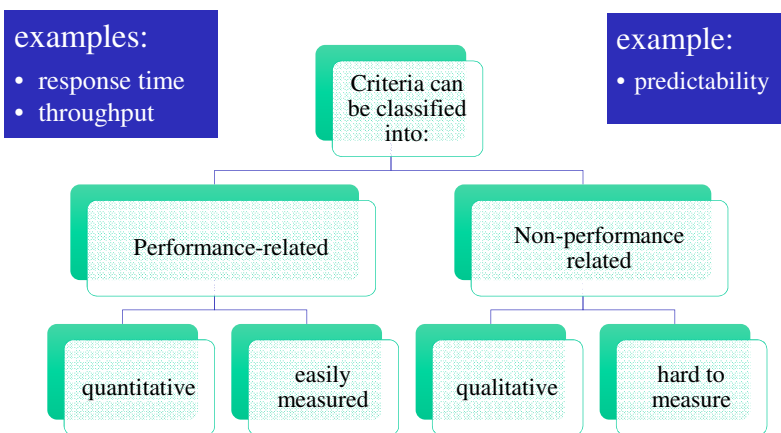

Short Term Scheduling Criteria

- User-oriented criteria
 - relate to the behavior of the system as perceived by the individual user or process (such as response time in an interactive system)
 - important on virtually all systems

Short Term Scheduling Criteria

- System-oriented criteria
 - focus in on effective and efficient utilization of the processor (rate at which processes are completed)
 - generally of minor importance on single-user systems

Short-Term Scheduling Criteria: Performance

Scheduling Criteria - User Oriented, Performance Related

- Turnaround Time
 - The interval of time between the submission of a process and its completion.
 - Includes actual execution time plus time spent waiting for resources, including the processor.
- Response Time
 - For an interactive process, this is the time from the submission of a request until the response begins to be received.
- Deadline
 - When process completion deadlines can be specified, the scheduling discipline should subordinate other goals to that of maximizing the percentage of deadlines met.

Scheduling Criteria - User Oriented, Other

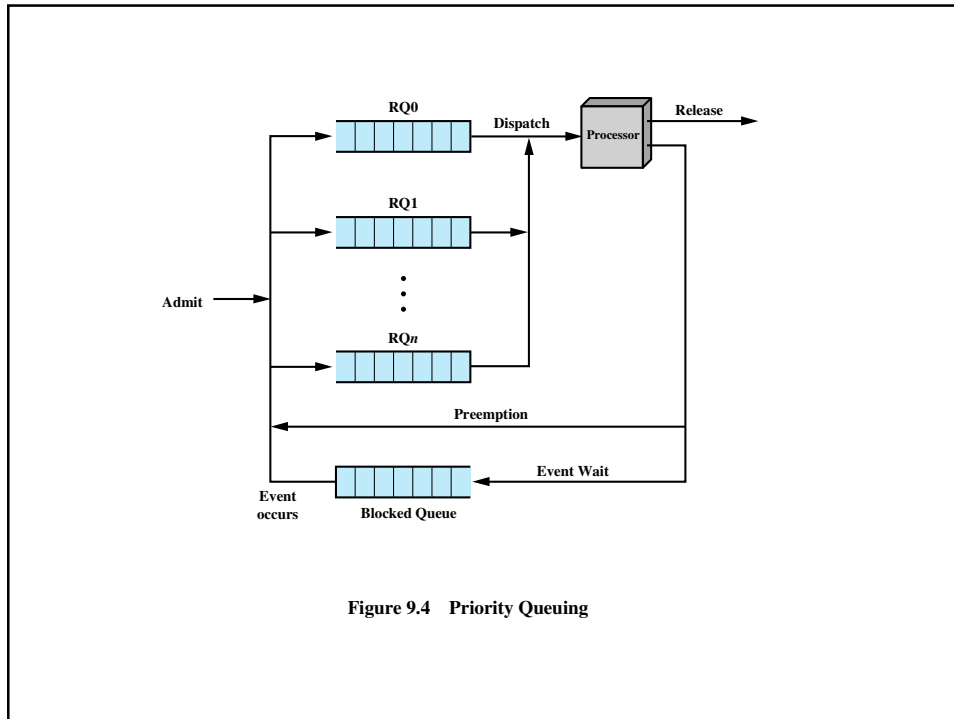

- Predictability
 - A given job should run in about the same amount of time and at about the same cost regardless of the load on the system.
 - A wide variation in response time or turnaround time is distracting to users.
 - It may signal a wide swing in systems workloads or the need for system tuning to cure instabilities.

Scheduling Criteria – System Oriented, Performance Related

- Throughput
 - The scheduling policy should attempt to maximize the number of processes completed per unit time.
 - This is a measure of how much work is being performed.
 - This clearly depends on the average length of a process but is also influenced by the scheduling policy.
- Processor utilization
 - This is the percentage of time that the processor is busy.
 - For an expensive, shared system, this is a significant criterion.
 - In single-user systems and in some other systems, such as real-time systems, this criterion is less important than some of the others.

Scheduling Criteria – System Oriented, Other

- Fairness
 - In the absence of guidance from the user or other system-supplied guidance, processes should be treated the same, and no process should suffer starvation.
- Enforcing priorities
 - When processes are assigned priorities, the scheduling policy should favor higher-priority processes.
- Balancing resources
 - The scheduling policy should keep the system resources busy, favoring processes that underutilize stressed resources.

Selection Function

- Determines which process, among ready processes, is selected next for execution
- May be based on priority, resource requirements, or the execution characteristics of the process

Selection Function

- If based on execution characteristics, then important quantities are:
 - w = time spent in system so far, waiting
 - e = time spent in execution so far
 - s = total service time required by the process, including e ; generally, this quantity must be estimated or supplied by the user

	FCFS	Round robin	SPN	SRT	HRRN	Feedback
Selection function	$\max[w]$	constant	$\min[s]$	$\min[s - e]$	$\max\left(\frac{w + s}{s}\right)$	(see text)
Decision mode	Non-preemptive	Preemptive (at time quantum)	Non-preemptive	Preemptive (at arrival)	Non-preemptive	Preemptive (at time quantum)
Through-Put	Not emphasized	May be low if quantum is too small	High	High	High	Not emphasized
Response time	May be high, especially if there is a large variance in process execution times	Provides good response time for short processes	Provides good response time for short processes	Provides good response time	Provides good response time	Not emphasized
Overhead	Minimum	Minimum	Can be high	Can be high	Can be high	Can be high
Effect on processes	Penalizes short processes; penalizes I/O bound processes	Fair treatment	Penalizes long processes	Penalizes long processes	Good balance	May favor I/O bound processes
Starvation	No	No	Possible	Possible	No	Possible

Decision Mode

- Specifies the instants in time at which the selection function is exercised
- Two categories:
 - Nonpreemptive
 - Preemptive

Nonpreemptive vs Preemptive

- Nonpreemptive
 - once a process is in the running state, it will continue until it terminates or blocks itself for I/O
- Preemptive
 - currently running process may be interrupted and moved to ready state by the OS
 - preemption may occur when new process arrives, on an interrupt, or periodically

Process Scheduling – An Example

Process	Arrival Time	Service Time
A	0	3
B	2	6
C	4	4
D	6	5
E	8	2

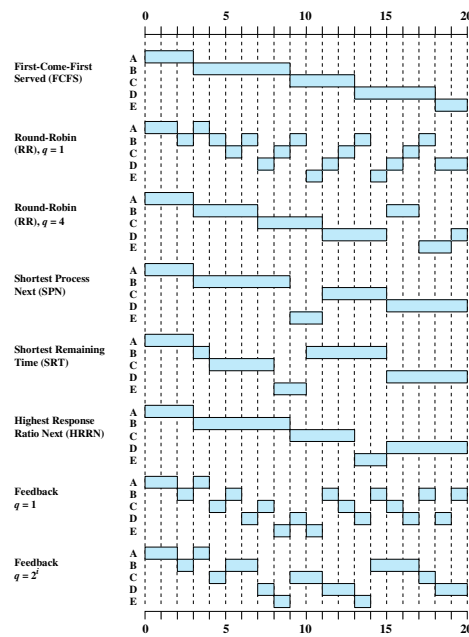

Figure 9.5 A Comparison of Scheduling Policies

First-Come-First-Served (FCFS)

- Simplest scheduling policy
- Also known as first-in-first-out (FIFO) or a strict queuing scheme
- When the current process ceases to execute, the longest process in the Ready queue is selected
- Performs much better for long processes than short ones
- Tends to favor processor-bound processes over I/O-bound processes

Round Robin

- Uses preemption based on a clock
- Also known as **time slicing** because each process is given a slice of time before being preempted
- Principal design issue is the length of the time quantum, or slice, to be used
- Particularly effective in a general-purpose time-sharing system or transaction processing system
- One drawback is its relative treatment of processor-bound and I/O-bound processes

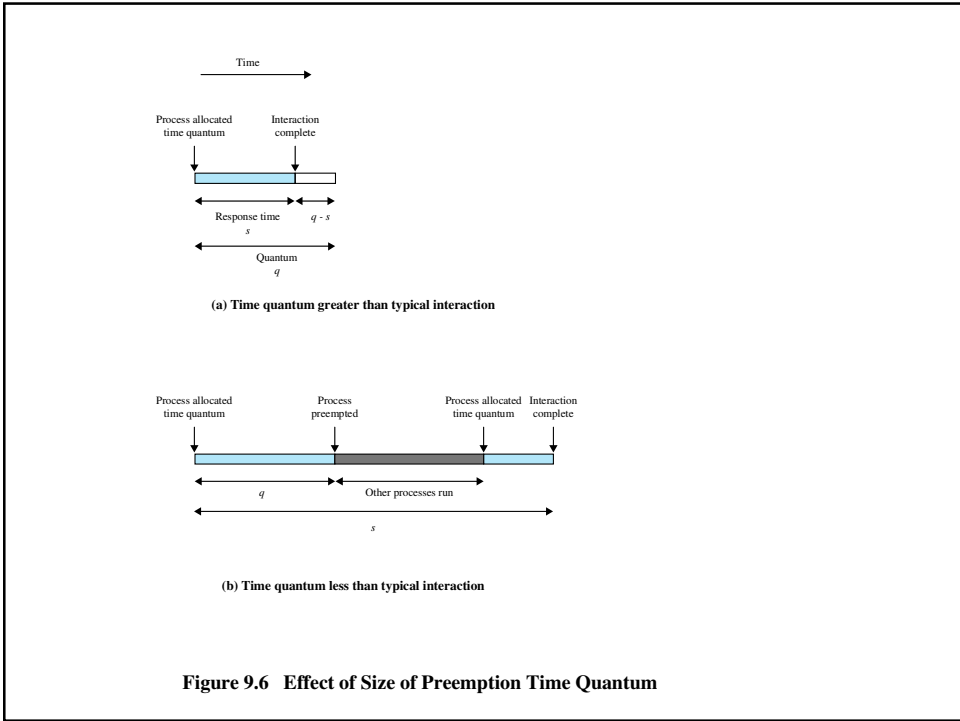

Figure 9.6 Effect of Size of Preemption Time Quantum

Process	A	B	C	D	E	
Arrival Time	0	2	4	6	8	
Service Time (T_s)	3	6	4	5	2	Mean

T_r/T_s	1.33	2.50	3.50	2.80	3.00	2.63

A Comparison of Scheduling Policies

Figure 9.7 Queuing Diagram for Virtual Round-Robin Scheduler

Refining the Round Robin

- New processes arrive and join the ready queue (FCFS scheduling).
- When a running process times out, it is returned to the ready queue.
 - When a process is blocked for I/O, it joins an I/O queue. Processes being released from an I/O are moved to an FCFS auxiliary queue; these processes preference in getting dispatched. They get the basic time quantum minus the total time spent running.

Shortest Process Next (SPN)

- Nonpreemptive policy in which the process with the shortest expected processing time is selected next
- A short process will jump to the head of the queue
- Possibility of starvation for longer processes
- One difficulty is the need to know, or at least estimate, the required processing time of each process
- If the programmer's estimate is substantially under the actual running time, the system may abort the job

Figure 9.8 Exponential Smoothing Coefficients

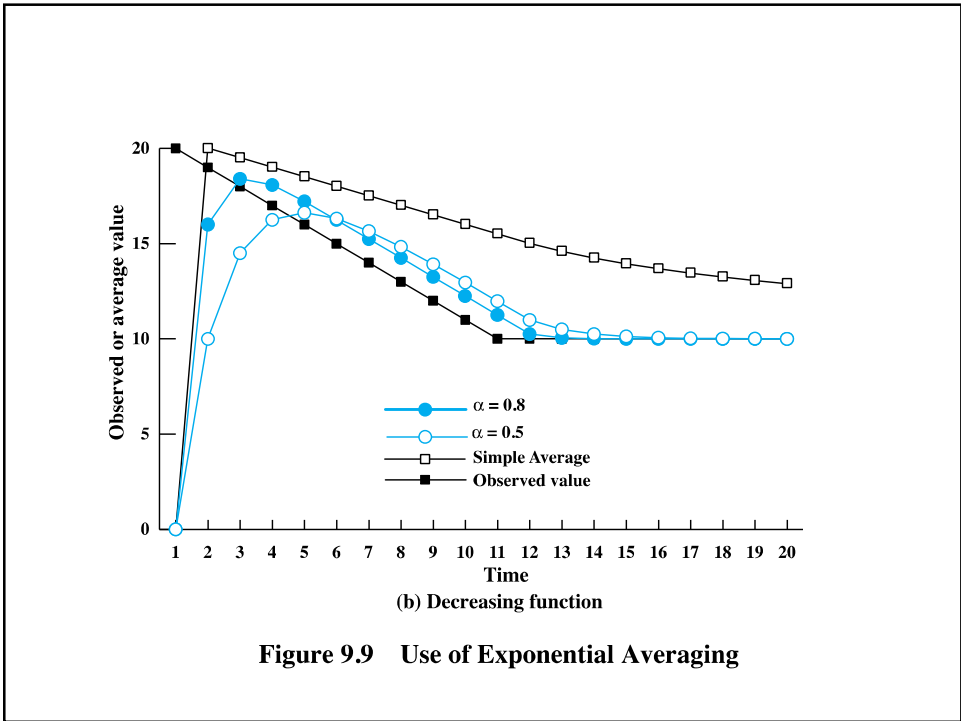

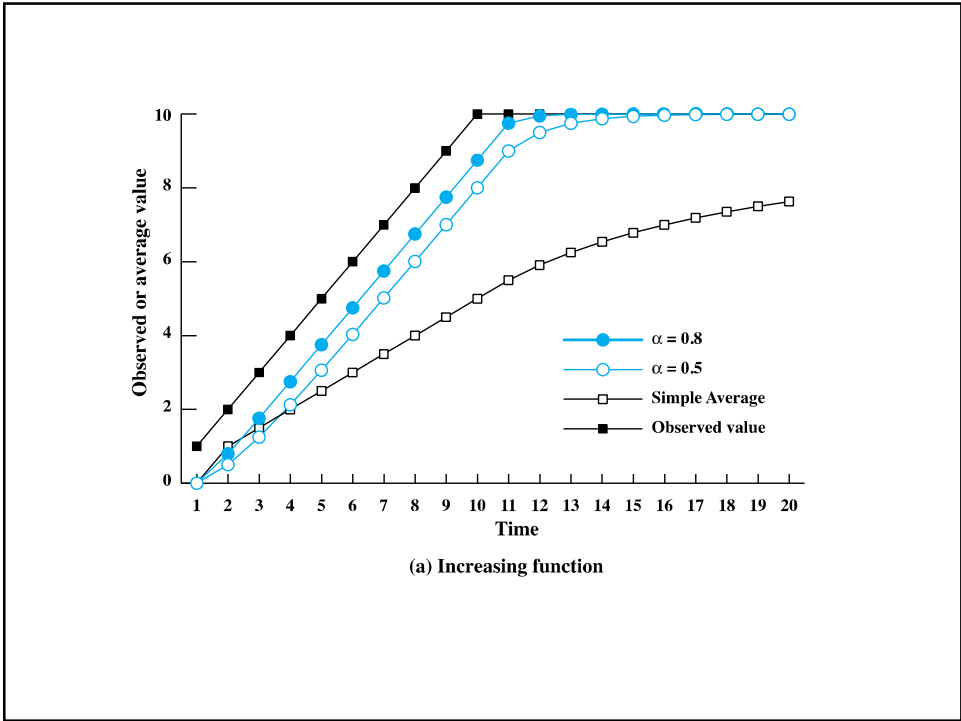

Figure 9.9 Use of Exponential Averaging

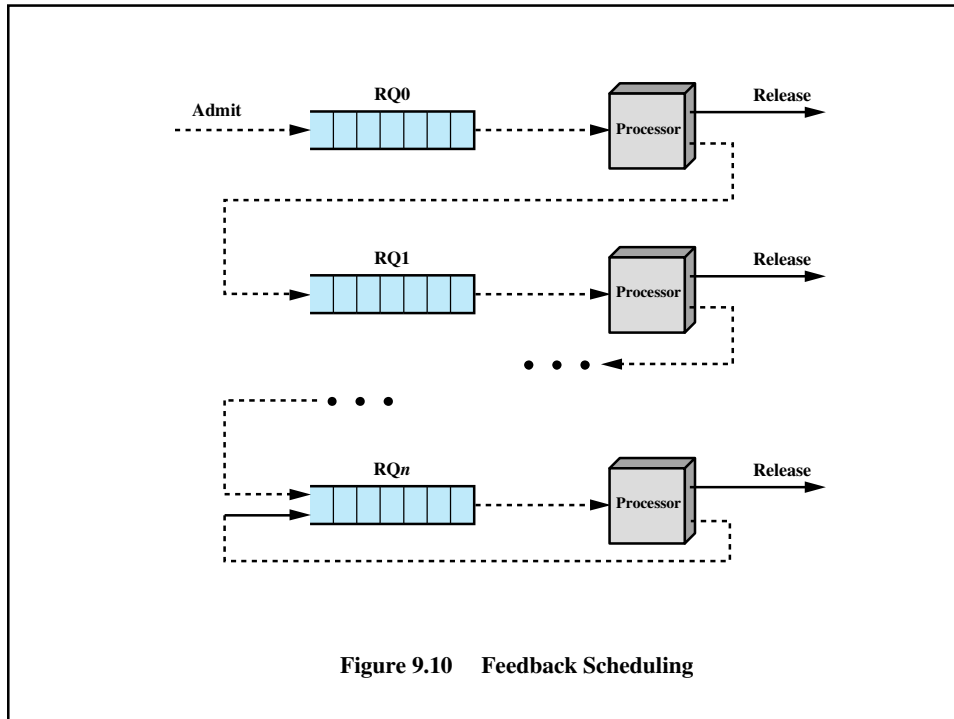

Shortest Remaining Time (SRT)

- Preemptive version of SPN
- Scheduler always chooses the process that has the shortest expected remaining processing time
- Risk of starvation of longer processes
- Should give superior turnaround time performance to SPN because a short job is given immediate preference to a running longer job

Highest Response Ratio Next (HRRN)

- Chooses next process with the greatest ratio
- Attractive because it accounts for the age of the process
- While shorter jobs are favored, aging without service increases the ratio so that a longer process will eventually get past competing shorter jobs

$$\text{Ratio} = \frac{\text{time spent waiting} + \text{expected service time}}{\text{expected service time}}$$

Performance Comparison

- Any scheduling discipline that chooses the next item to be served independent of service time obeys the relationship:

$$\frac{T_r}{T_s} = \frac{1}{1 - \rho}$$

where

T_r = turnaround time or residence time; total time in system, waiting plus execution

T_s = average service time; average time spent in Running state

ρ = processor utilization

- Assumptions: 1. Poisson arrival rate.
 2. Priority 1 items are serviced before priority 2 items.
 3. First-come-first-served dispatching for items of equal priority.
 4. No item is interrupted while being served.
 5. No items leave the queue (lost calls delayed).

(a) General formulas

$$\lambda = \lambda_1 + \lambda_2$$

$$\rho_1 = \lambda_1 T_{s1}; \quad \rho_2 = \lambda_2 T_{s2}$$

$$\rho = \rho_1 + \rho_2$$

$$T_s = \frac{\lambda_1}{\lambda} T_{s1} + \frac{\lambda_2}{\lambda} T_{s2}$$

$$T_r = \frac{\lambda_1}{\lambda} T_{r1} + \frac{\lambda_2}{\lambda} T_{r2}$$

(b) No interrupts; exponential service times

$$T_{r1} = T_{s1} + \frac{\rho_1 T_{s1} + \rho_2 T_{s2}}{1 - \rho_1}$$

$$T_{r2} = T_{s2} + \frac{T_{r1} - T_{s1}}{1 - \rho}$$

(c) Preemptive-resume queuing discipline; exponential service times

$$T_{r1} = T_{s1} + \frac{\rho_1 T_{s1}}{1 - \rho_1}$$

$$T_{r2} = T_{s2} + \frac{1}{1 - \rho_1} \left(\rho_1 T_{s2} + \frac{\rho T_s}{1 - \rho} \right)$$

Fair-Share Scheduling

- Scheduling decisions based on the process sets
- Each user is assigned a share of the processor
- Objective is to monitor usage to give fewer resources to users who have had more than their fair share and more to those who have had less than their fair share

Time	Process A			Process B			Process C

Figure 9.16 Example of Fair Share Scheduler—Three Processes, Two Groups

Traditional UNIX Scheduling

- Used in both SVR3 and 4.3 BSD UNIX
 - these systems are primarily targeted at the time-sharing interactive environment
- Designed to provide good response time for interactive users while ensuring that low-priority background jobs do not starve
- Employs multilevel feedback using round robin within each of the priority queues
- Makes use of one-second preemption
- Priority is based on process type and execution history

Scheduling Formula

$$CPU_j(i) = \frac{CPU_j(i-1)}{2}$$
$$P_j(i) = Base_j + \frac{CPU_j(i)}{2} + nice_j$$

where

$CPU_j(i)$ = measure of processor utilization by process j through interval i

$P_j(i)$ = priority of process j at beginning of interval i ; lower values equal higher priorities

$Base_j$ = base priority of process j

$nice_j$ = user-controllable adjustment factor

Bands

- Used to optimize access to block devices and to allow the operating system to respond quickly to system calls
- In decreasing order of priority, the bands are:

Time	Process A		Process B		Process C	
	Priority	CPU count	Priority	CPU count	Priority	CPU count
0	60	0	60	0	60	0
		1
